Effect of Different Diets with Sugar-Peptide Beverage on Oxidation of Carbohydrate and Lipid after Exercise

Ronghua Liu*

Chang'an District of Xi'an Chang'an Road No. 199 Shaanxi Province, Shaanxi Normal University, China

Abstract: Human tests show that long-term high-fat diet adaptation can increase fat oxidation in the exercise significantly than high-carbohydrates. Fewer studies focus on single high fat diet on glucose and lipid metabolism and the change of fat oxidation. This test attempts to use respiratory quotient as an effective indicator to reflect the body's metabolism of glucose and lipid and evaluate the oxidation of different dietary conditions in order to provide a direct basis for people’s reasonable diet.

Keywords: Different diets, exercise, oxidation of carbohydrate, oxidation of lipid, sugar-peptide beverage.

1. INTRODUCTION

In recent years, residents have changed a lot of food choices with economic development, people's incomes increased and market food enriched. Dietary patterns tend to change unhealthy to the high-fat, high-energy and low-grain due to increasing in consumption of meat, oils and fats and a fall in consumption of cereals, pulses and vegetable [1]. And this will affect people's health. Chinese nutrition society combined with our actual dietary pattern and developed dietary with suitable fat intake for adults (AIS) within the total energy intake in 20%-30%. Therefore, it is the low-fat diet with the requirement below 20% and the high-fat diet with the requirement above 30%. Dietary lipids (fat, cholesterol and fatty acids) is closely related to health. As living standards improve and market supply of animal food and vegetable oil is becoming richer, residents obviously increased in dietary fat intake [2]. Some residents in economically developed regions in China is particularly evident whose fat percentage of total energy intake has exceeded 30%. Therefore, how to control fat and cholesterol intake and adjust the fatty acid composition to reduce obesity, cardio-cerebral vascular disease, cancer and other chronic diseases have become hot issues in the field of nutrition [3].

In the 20th century, there have been several kinds of weight-loss diets. They advocate free for them to eat foods which are rich in protein and fat, but they refuse foods with high carbohydrates. One of them is Marri diet in 1949. The following is Prudent diet, Gordon diet, Donalds diet, Yudkin diet and other similar weight-loss diet. This dietary law is based on the theory of carbohydrates, particularly sugar which has a lower satiety value and cause a "artificial taste". People are interested in dietary supplementation with dietary fiber. Researchers believe that diet which is rich in dietary fiber can reduce the total energy intake and help control weight without detailed numerical calculation of dietary energy. Most popular diets right now is to limit dietary fat. Many nutritionists and other health professionals have advocated to permanently maintain a low-fat diet in order to lose weight and maintain their weight on the low [4].

We generally use nutrition to measure dietary standards. In terms of energy research, the FAO determines the minimum calorific value of food to be 2300 kcal which is relatively comfortable of 2600 kcal [5]. The World Health Organization (WHO) puts forward that the real intake of fat should account 15% to 30% for total dietary energy. In terms of protein intake, it is recommended that the animal protein account for 62.50 in United States food pyramid. Physical activity can enhance the ability to regulate blood sugar and insulin sensitivity and it also would help to reduce the incidence of CVD. Once we stop exercising, benefit for exercise will soon disappear. So acute effect of exercise on body may improve glucose tolerance and insulin resistance which is an important part of critical points. Therefore studies of acute exercise is also essential.

The rest of the paper is organized as follows. In Section 2, research methods is summarized briefly. In Section 3, experimental is described. In Section 4, experiments results are presented and the results are discussed. Finally, a conclusion is provided in Section 5.

2. RESEARCH METHODS

2.1. Subject

There are eight healthy adult males volunteered for the experiment who meet following conditions: non-smokers, age 24-27, weight normal, no metabolism sex disease and diabetes, and often participate in running and other physical activities. The Subjects must have movement endurance level who can complete movement test by experiment requirements as in Table 1.
2.2. The Preliminary Experiment

We use the power car to do movement tests. Cardiopulmonary exercise tests for measuring oxygen uptake and respiratory exchange ratio. Telemetry heart rat monitor record heart rate. The lab environment is as follows: temperature 19-23 0C, relative humidity 30-50%, air pressure 1014-1032 mbar.

Motion mode is incremental exercise tests in s vehicle. Subjects have 5 minutes for preparatory activities with 60 W to suit the load and bike speed, and then do exercise test according to the set load. The experiments collect exhaled breath and record heart rate in the testing process [6-8].

2.3. Experiment Scheme

Experiments select four different diets: Diet CC(high sugar diet and sugary drinks), Diet FC(high fat diet and sugary drinks), Diet CP(high sugar diet and polysaccharide peptide drink) and Diet FP(high fat diet and polysaccharide peptide drink). They contain the equal amount of food. Subjects should intake the same food as usual for the lunch and dinner before the experiment. They dominated by bland foods and avoid eating fatty foods [9, 10].

The experiment uses self-control and balance in overlapping to test subjects which conducts four times. Each test interval of at least 2 times is 7 days in order to eliminate the effects of previous tests. Subjects were divided into 4 teams, and there are 2 subjects every day from first week to the fourth week as shown in Table 2. The two subjects must eat the same food every day. Feeding sequence is as follows:

2.4. Detection Index

A series of indicators need to be tested. (1) blood glucose. We use test paper method to measure fingertip blood. (2) serum hormone. Insulin was measured by chemiluminescence method. Leptin was measured by ELISA method. Relation of standard curve is as follows:

\[ Y = 1.6964X^2 - 19.464X + 55.179 \quad (R^2 = 0.9737) \quad (1) \]

(3) metabolic markers. There is a series of breathing gas metabolism, including respiratory quotient, energy consumption, CHO oxidation rate, FAT oxidation rate, CHO%, FAT% and so on. We use the following formula to estimate the total CHO and total fat oxidation speed.

\[ CHO = 4.585 \times VCO_2 - 3.226 \times VO_2 \quad (2) \]

\[ FAT = 1.695 \times VO_2 - 1.701 \times VCO_2 \quad (3) \]

2.5. Statistical Analysis

Experimental data is indicated by mean plus standard error. Statistical analysis is completed by SPSS software. Firstly, we use K-S method to examine if the indicators data are normally distributed, and then parametric statistical analysis. Secondly, we define two variables corresponding to two factors in this study. We build a 2X2 two factor single variable database according to levels of each factor. Generalized linear model is used for a single dependent variable multi-factor analysis of variance in order to analyze interaction effects between these two factors of high-fat and skin supplementation. We use GLM multivariate variance analysis to test differences between the dependent variable and multiple dependent variables on the same point in time. Significant test results take for P<0.05 and unsignificant test results take for P<0.01.

3. EXPERIMENTAL RESULTS

3.1. Food Intake Results

Drink energy ingredient is as follows in Table 3.

The nutritional content of food is as follows in Table 4.

3.2. Effect of Different Diet on Glucose Metabolism-Related Indicators

We have measured the glucose after 45 minutes of meals. The CC group is significantly higher than group of FC, CP and FP and it has significantly differences (P<0.05). Analysis results showed that main effect of polysaccharide on glucose has statistics meaning at the moment (F=5.601, P=0.026). And main effect of high fat on glucose also has

![Fig. (1).](image1.png) Effect of aerobic exercise and different diets on blood glucose levels.

![Fig. (2).](image2.png) Effects of different diet and aerobic exercise on serum insulin.

Statistics meaning (F=13.336, P=0.001), but they have no interactive effect. On the other hand, we have measured the glucose after 45 minutes of sports. The CC group is significantly higher than group of FC. Analysis results showed that main effect of high fat on glucose also has statistics meaning (F=5.386, P=0.028) Fig. (1).

Group of CC and CP have no significantly change on serum TG levels in the experiment. Serum TG of group of FC and FP trends similar. Serum TG levels don’t significantly increase after meals, but were significantly higher than in the early morning quiet time after exercise (P<0.05). TG levels were significantly higher than in the early morning quiet time and after meals when exercise of 45 minutes (P<0.01). Serum TG levels don’t significantly increase after meals in group of PF, but were significantly higher than in the early morning quiet time after exercise (P<0.01) and also were significantly higher than after meals Fig. (2).

The TG levels in group of CC and FC differ significantly after exercise for 45 minutes (P<0.05), and were significantly different with group of FP (P<0.01). The TG levels in group of FP and CP differ significantly (P<0.05),
and were significantly different with group of CC (P<0.01). Analysis results showed that main effect of high lipid on serum TG level was statistically significant (F=11.281, P=0.002) as shown in Fig. (3).

3.3. Discussion and Analysis

Theoretically speaking, the activity when you take sugar diet or soda before exercise can cause hypoglycemia in sports. Research has also proved that eating at this time will have a negative effect on their scores. This experiment observed groups of CC and CP are high in blood sugar and insulin levels after exercise for 45 minutes which will help promote the glycogen recovery after exercise.

Studies have shown that metabolic status also affects the rate of fat oxidation in addition to the impact of the type of fatty acids. Hunger and chronic exercise conditions can also lead to increased lipolysis and oxidation. Glucose and insulin levels can inhibit the oxidation of fatty acids on substrates and hormones Fig. (4).

CONCLUSION

In this paper, we can get some results. (1) RQ will reduce after high fat diet and will increase after high sugar diet. RQ after high sugar diet will rise more than after high fat diet. (2) High sugar diet may improve glucose oxidation rate and proportion of energy supply. High fat diet may improve fat oxidation rate and proportion of energy supply. After the intake of the same high-fat diet and high sugar diet, dietary energy intake of high fat diet is higher than high sugar diet. But energy expenditure did not increase after a high fat diet which can lead to the body's energy balance. (3) Candy skin drinks can promote fat oxidation during and after exercise after high fat diet.

It is desirable to further apply the analysis results to solving those more complex real-world health problems and it will be our further work.
