

$$S_{rM}(t, f_r) = \text{rect}\left(\frac{t}{T_a}\right) \text{rect}\left(\frac{f_r}{kT_p}\right) \exp\left[j\left(K_r(R_a - R_r)\right)\right] \quad (2)$$

Where $K_r = 4\pi(f_c + f_r)/c$ is the size of the radial wave-number. For further analysis, make plane wavefront approximation, ignoring the effect of amplitude information. The projections of the wavenumber vector, in azimuth and range directions are represented by $K_x = K_r \cos\varphi \sin\theta$, $K_y = K_r \cos\varphi \cos\theta$ respectively. In the wavenumber domain, formula (2) can be indicated as below:

$$S_{rM}(K_x, K_y) = \exp\left[j(x_i K_x + y_i K_y)\right] \quad (3)$$

It can be seen from the above equation that, there is a direct relationship between the echo signal representation and the target position's information, which can obtain target position's information by two-dimensional Fourier transform. The improvement of the computational efficiency is generally implemented through two times of FFT transform, which requires that the processed signal must satisfy the characteristic of uniform sampling in wavenumber domain. However, the real echo signal is arranged with polar format, in the wavenumber's frequency domain. While through two-dimensional interpolation, it can be converted into the rectangular format arrangement.

MOTION COMPENSATION ALGORITHM

Due to the interference of external environment, and the imprecision of its control system when capture data, the radar platform cannot maintain the ideal state of motion, leading to echo signal's deviation of phase in azimuth, which needs for motion compensation processing, in the imaging procedure to correct the phenomenons of defocus and distortion caused by it, just in order to improve the final image quality.

The platform's unideal motion mainly consists of two aspects [19-21]: Deviations from the ideal track translational motion and the posture rotation of the platform's own. The latter influence can be ignored after the inertial navigation system's (INS) control, while the former effect can not be removed completely, which needs compensation for imaging errors that its causes. Here will mainly study the motion compensation based on echo data.

RANGE ALIGNMENT ALGORITHM

Range alignment is also called the envelope alignment [22, 23] - a key technology of ISAR imaging. By eliminating the adjacent echo's dislocation in the range direction, realize the envelope alignment of the one dimensional range profile, to eliminate the phase error caused by the range translation. The premise of its use is that the envelopes of adjacent echo signals, received in data acquisition have strong similarities. Spotlight SAR is generally for small scene and high

resolution imaging, moreover, the rotational angle of carrier aircraft, corresponding to adjacent echoes, is generally less than 0.01° , so the scattering point's walk is very small, making the real envelopes of adjacent echo very similar, which is the key factor to introduce range alignment technique to Spotlight SAR imaging.

This paper mainly uses the envelope correlation method and the accumulated envelope correlation method, to implement them and contrast the imaging results. Correlation method is widely used as a range alignment algorithm, mainly based on the similarities between adjacent echoes in the domain of one-dimensional range, using the cross-correlation method that compensates translational motion based on the delay corresponding to adjacent echoes' peaks, to obtain better alignment for adjacent envelope. A certain fixed one of the echo signal is set as the reference signal, and generally we choose the first echo signal or the one from Synthetic aperture Center. This algorithm has high alignment accuracy, but with accumulation of phase errors inevitably, leading to the phenomena of envelope's drift and envelope's jumpy-changing. While the accumulated envelope correlation method sets the weighted sum of all the previous aligned echoes' one-dimensional range profiles. The single echo's error has little effect on the processing, so the phenomena of sudden jumpy-changing caused by the error accumulation is greatly reduced.

In reference [23], one global optimal method is proposed that based on amplitude correlation of all the echoes, and it is possible to formulate the process as follows:

$$(\tau_2, \tau_3, \dots, \tau_M) = \arg \max_{\tau_2, \tau_3, \dots, \tau_M} \sum_{i=1}^M \sum_{j=i+1}^M |S_i(n - \tau_i)| \cdot |a(i)S_j(n - \tau_j)| \quad (4)$$

Where M represents the times of echo, and $a(j)$ represents the weighted coefficient.

When determining the weighted coefficient, consider that the closer echo with the fixed echo, has stronger correlation, so we often set bigger weights for the closer adjacent echoes. However, if we want to eliminate the jumpy-changing errors' distance image, we need to set the weights corresponding to the closer adjacent echo to be smaller. Combined, the weighted coefficients are generally set to be 1 uniformly.

MD-PGA AUTOFOCUS ALGORITHM

The MD-PGA algorithm [24] is just an autofocus algorithm combining PGA and MD algorithm. Consider dividing the whole aperture into multiple sub apertures, and then image the sub aperture, and estimate the phase error of each sub aperture with PGA algorithm. While the linear phase error between the sub aperture images, focused with PGA is estimated using MD algorithm. After that, piece together the phase error of each sub aperture and the linear phase error between the sub apertures, making the phase error of the

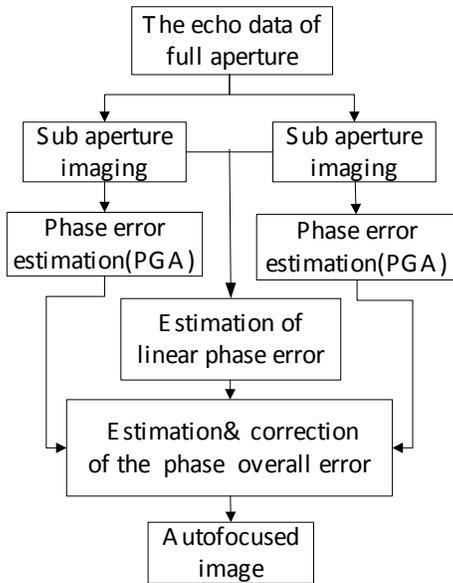

Fig. (2). Original MD-PGA process.

whole aperture is continuous. The MD-PGA process when divided into two sub apertures is showed as Fig. (2), and the process of multiple sub apertures is similar.

According to the analysis of the original MD-PGA process, it can be known that the influence of the linear phase error is reduced, but there are still some defects without estimation and compensation on high-order phase error of the adjacent sub apertures. This paper improved the original MD-PGA algorithm, and the improved flow diagram is shown in Fig. (3). Process the imaging results of the full aperture echo data with PGA algorithm, followed with phase error estimation and phase correction of echo data, and the full aperture data after phase correction is divided into several sub apertures to image. Then estimate the linear phase error between the sub aperture imaging results using MD algorithm, after that, combine the linear phase error estimated by MD algorithm and the full aperture imaging phase error estimated with PGA to construct a new correction factor of the phase error. Finally correct the phase error of the full aperture echo data with the new correction factor, and the focused image is obtained. The improved MD-PGA algorithm can not only correct the linear phase error of the original PGA process, but also compensate the high-order phase error between the sub apertures.

CORRECTION OF WAVEFRONT CURVATURE ERROR

In section2, the derivation of PFA imaging principle in the process, takes the planar wavefront assumption. But when the imaging area is too broad, the error brought by planar wavefront assumption can't be ignored, cause the reduced imaging distance and the need of high resolution,

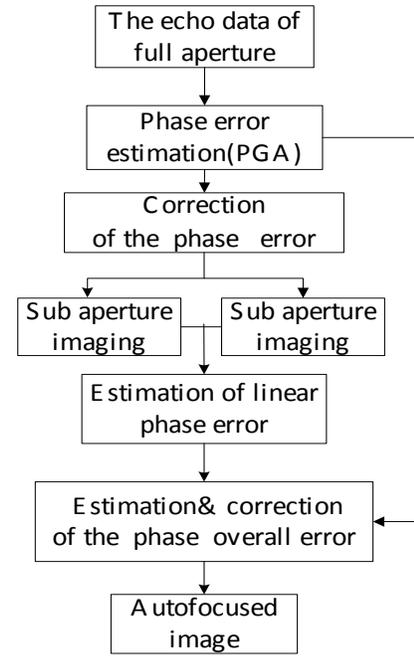

Fig. (3). Improved MD-PGA process.

require correction. Considering the compensation of the wavefront curvature error, this paper makes some improvements on the method of Space-variant post processing, and the algorithm deals with the PFA imaging result directly, with the correction of wavefront curvature in the complex image domain.

Makes two-dimensional Taylor series expansion for the echo data's expression (3) directly in wavenumber domain, and the formula below can be obtained.

$$S_{rM}(K_x, K_y) = \exp[jk_r(R_a - R_t)] = \exp\left[j\frac{\sqrt{K_x^2 + K_y^2}}{\cos\varphi}(R_a - R_t)\right] \quad (5)$$

$$= \exp\left\{j\left[\begin{matrix} c_{01}K_x + c_{10}(K_y - K_c) + c_{11}K_x(K_y - K_c) + c_{20}K_x^2 \\ + c_{02}(K_y - K_c)^2 + \dots \end{matrix}\right]\right\}$$

Where $K_c = \frac{4\pi}{c} f_c \cos\varphi_0$ is the bias of wavenumber K_y in

Y direction. The specific derivation process is described in [25], and the coefficient values can be calculated with Taylor expansion formula. From the formula (5) can know that the influence of wavefront curvature mainly are: a). defocus and blur in the azimuth caused by quadratic phase error, which can be corrected by two-dimensional spatial filter. Consider that the defocusing phenomena mainly occur in azimuth direction, the spatial filtering is only designed for one-dimensional azimuth filtering. b). geometric distortion of the target's position caused by first-order linear phase error, which can be corrected with resampling in the spatial domain. The process is illustrated in Fig. (4).

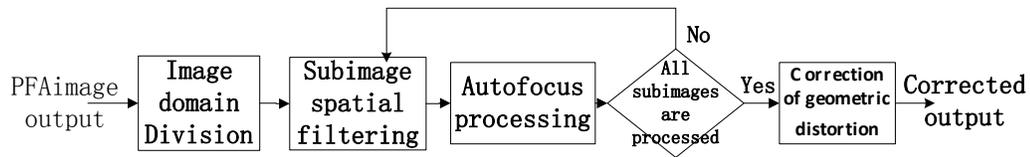

Fig. (4). Space-variant post processing.

Table 1. Parameters of real data.

T_p	B_r	f_s	f_c	f_{PRF}	T_s	f_{GPS}
5 μ s	200MHZ	480MHZ	17.15GHZ	1000HZ	56s	151HZ

The high resolution imaging general flowchart of spotlight SAR is shown in Fig. (5).

EXPERIMENTAL RESULTS

In this paper, the measured data processed are the echo data from airborne spotlight SAR acquisition, and the specific parameters are shown in Table 1. We chose 2048 pulses'echo from the full aperture to process. The corresponding squint angle is 0.3348rad, while the range resolution is 0.75m and the azimuth resolution is about 0.4m.

Fig. (6). Directly imaging.

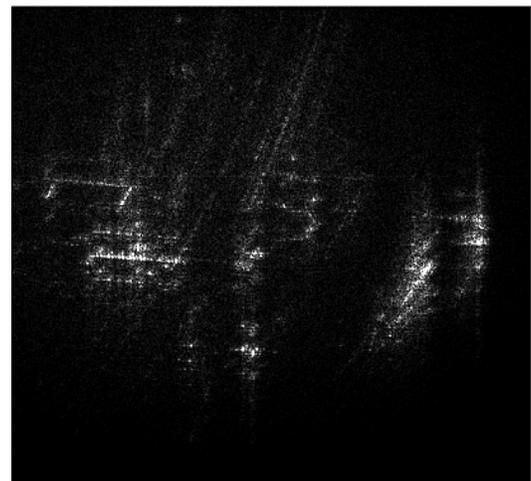

Fig. (7). Envelope correlation alignment result.

Fig. (6) is the directly imaging result without motion compensation, looking fuzzy. After using the envelope correlation method and the global accumulated envelope correlation method to achieve the range alignments, the imaging results are shown in Fig. (7) and Fig. (8) respectively. From the imaging results, it can be obviously seen that the imaging

(a) MD-PGA

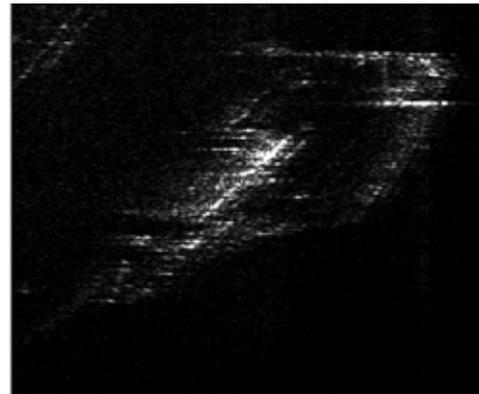

(b) Improved MD-PGA

Fig. (9). Autofocus imaging results.

result in Fig. (8) focuses better than in Fig. (6), and the result has been significantly improved; While there are serious false contours and defocused phenomenon in Fig. (7). Then we evaluate the images objectively from the aspects of image entropy and contrast ratio. Fig. (6) - entropy: 11.3927, contrast ratio: 26.4728; Fig. (7) - entropy: 11.607, contrast ratio : 23.4534; Fig. (8) - entropy: 11.0467, contrast ratio: 33.8693. It can be known that compared to the formers,

(a) MD-PGA

(b) Improved MD-PGA

Fig. (10). Partial enlargement of autofocus imaging results.

Fig. (8)'s entropy decreases, while its contrast ratio increased significantly, so the image quality has been improved obviously.

Range alignment is used as the motion compensation of range translation. The processing results of measured data shows that the imaging quality has been improved a lot, but there are still some obvious defocus phenomena, which need further motion compensation to correct.

Contrast the autofocus Imaging results, Fig. (9a) - entropy: 10.6567, contrast ratio: 53.7549; Fig. (9b) - entropy: 10.5778, contrast ratio: 54.8773. It is thus clear that the autofocus imaging results of improved MD-PGA is of smaller entropy and bigger contrast ratio. Besides, their partial enlargement of autofocus imaging results, shown in Fig. (10), reveal that improved MD-PGA autofocus effect is better.

The effect of the correction of wavefront curvature error of autofocus imaging results is shown in Fig. (11). Since there is no obvious geometric distortion phenomenon, we only adopt Space-variant post filtering for image to correct the phase error generated by the wavefront curvature. Compared with Fig. (9b), it is obvious that the focusing effect in Fig. (11) improves, after correcting the wavefront curvature error. Calculate the Entropy and contrast ratio of Fig. (11), and we can learn that, the image entropy decreases

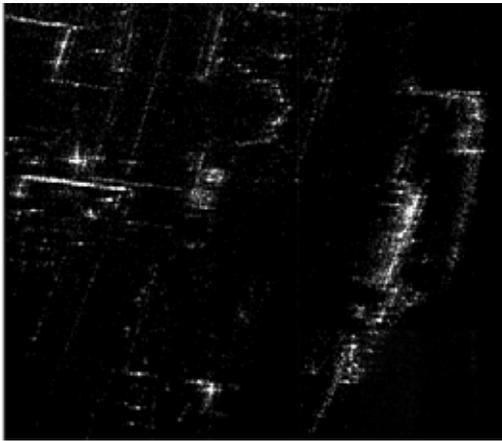

Fig. (11). Wavefront curvature corrected results.

although not significantly, meanwhile the contrast ratio raises markedly from the original 53.7549 to 71.556.

CONCLUSION

This paper combining the range alignment technology in ISAR, presents an effective motion compensation method of spotlight SAR, furthermore, it takes improved Space-variant post filtering algorithm to compensate the phase error caused by wavefront curvature. The analysis and processing of the measured data, have verified the feasibility and effectiveness of this method in practical application.
