We have simulated formamide, water–formamide, and water–ethanol mixtures (the 50–50 % solution) of  $\rho = 0.7\text{--}1.0$  g/cm<sup>3</sup>.

The MD simulation results for the formamide(f)+water(w) and ethanol(e)+water(w) solutions and surface interactions, which are summarized below, are shown for  $\rho \approx 0.8$  g/cm<sup>3</sup> = 50%(f)+50%(w) (1152 formamide and 1152 water molecules). The MD simulation results of the formamide(f) solution and surface interactions, which are also summarized below, are shown for  $\rho \approx 1.0$  g/cm<sup>3</sup> = 100%(f) (2304 formamide molecules).

The bulk TiO<sub>2</sub> (anatase) phase was defined by the unit cell lattice vectors of the following lengths:  $a_0 = b_0 = 3.785$  Å and  $c_0 = 9.514$  Å. As the adsorbing surface, we have composed in total four layers of 420 TiO<sub>2</sub> molecules (5040 = 1680 (Ti) + 3360 (O) atoms).

The bulk Pt<sub>4</sub> (platinum) phase was defined by the unit cell lattice vectors of the following lengths:  $a_0 = b_0 = c_0 = 3.923$  Å. As the adsorbing surface, we have composed in total four layers of 784 Pt<sub>4</sub> molecules (3136 (Pt) atoms).

The corresponding system sizes and molecular composition of 50-50% formamide-water and ethanol-water solutions and their densities are specified in Table 2.

**Table 2. The Geometry Details and Molecular Composition of the Simulated Models**

| System size  | X, Å  | Y, Å  | Z, Å  | $\rho$ , g/cm <sup>3</sup> | Ewald Parameters<br>( $k_1, k_2, k_3$ ) |
|--|-------|-------|-------|----------------------------|---|

| (Pt) <sub>3136</sub> (H <sub>2</sub> O) <sub>3456</sub> (C <sub>2</sub> H <sub>5</sub> OH) <sub>10368</sub>                | 54.92 | 54.92 | 69.22 | 0.76                       | 22, 22, 28                              |

A classical molecular dynamics study was performed using the DL\_POLY\_4.03.3 [28] general-purpose code. The NVT ensemble at  $T = 300$  K in conjunction with a Nosé-Hoover thermostat with the three dimensional Ewald summation and the Verlet leapfrog scheme were employed. To calculate electrostatic forces, the Ewald sum was used; the automatic optimization parameter was  $f = 1.0 \cdot 10^{-4}$ ; and the convergence parameter was  $0.24375$  Å<sup>-1</sup>. The integration time step of the dynamic equations of motion was 1 fs. All simulations were periodic in three dimensions.

For the formamide molecule, the force field parameters were chosen from the DL\_FIELD database [29], which, in their turn, had been taken from the CHARMM package [30].

The detailed formamide and ethanol potential and force field topology (chemical, angular, and dihedral bond parameters, atomic charges, etc.) are described below in Tables 3-5.

**Table 3. Intermolecular Lennard-Jones (LJ) Parameters for the Ethanol and Formamide Interactions with the TiO<sub>2</sub> and Pt Surfaces and Water Molecules. The Geometry of the Ethanol, Formamide, and Water Molecules is Shown Separately**

For the anatase surface, the force fields as reported by Kavathekar *et al.* [31] and Guillot *et al.* [32] were used. For the TiO<sub>2</sub> surface, the potential parameters were developed by Matsui and Akaogi [33]. The metallic substrate used was cubic Pt, which has the formula Pt<sub>4</sub>. It was arranged in 8 layers numbering a total of 3136 atoms. The lattice constant was  $a = 3.923 \text{ \AA}$ . All the pa-

parameters of platinum were taken from EIM databases and dataset website supported by the Russian Foundation for Basic Research [34]. (Table 6) represents the Buckingham (buck) potential parameters of the TiO<sub>2</sub> surface [33] and Sutton and Chen (SC or st-ch) potential parameters of the Pt surface [35].

**Table 6. The Force Field Potentials and Parameters for TiO<sub>2</sub> and Pt Surfaces**

| <b>Buckingham potential for TiO<sub>2</sub>: <math>A_{ij}\exp(-r_{ij}/\rho_{ij}) - C_{ij}/r_{ij}^6</math></b>                        |                                  |  |   |   |

For water, an SPC rigid body model was used [36–38]. The water bond angles and lengths were not constrained; the water potential parameters are also shown in (Table 3).

The van der Waals (vdW) interactions between the solutions (formamide–water and ethanol–water) and surfaces (TiO<sub>2</sub> and Pt) were represented by the Lennard–Jones (LJ) potential. The pair potential parameters from [39] was used for the Pt–N interaction. The cross-interaction parameters for formamide–water, ethanol–water, and surfaces (TiO<sub>2</sub> and Pt) are shown in (Tables 3).

A parallel Shake algorithm expressed in terms of the domain decomposition strategy for constraining the rigid and other chemical bonds was used [28]. The MD simulations were realized in the temperature range of 250 K to 400 K with a step of 25 K.
