Fig. (S1). Structure and nomenclature of cholesterol (A), 5- $\alpha$-cholestan-3-one (B) and their diastereomers 10- $\alpha$-cholesterol ( $\mathbf{C}$ ) and $5-\beta$ -cholestan-3-one (D).

## QUALITY FACTOR FOR VALIDATION OF FITS:

To compare fits of measured RDCs against different structural models, a quality factor for these fits is necessary. On the one hand it should consider how strong measured and back-calculated values differ and, on the other hand, it should take into account the experimental error of the measured values. This is described by $\chi^{2}$ defined as:

$$
\chi^{2}=\sum^{n}\left(\frac{x_{\text {meas. }}-x_{\text {calc. }}}{\Delta x_{\text {meas. }}}\right)^{2}
$$

with $\mathrm{x}_{\text {meas. }}$ and $\mathrm{x}_{\text {calc. }}$ being the measured and back-calculated values, respectively, and $\Delta \mathrm{x}_{\text {meas. }}$. being the experimental errors of $\mathrm{x}_{\text {meas }}$. As $\chi^{2}$ increases with an increasing number n of measured values, we found the best measure for the quality of a fit would be the normalized $n / \chi^{2}$, which should be as high as possible.
The quality factor is optimized for the comparison of different fits to a single set of experimental RDCs, including the important individual maximum error estimates for the measured values. Other quality factors are available which are adapted to other specifications. Therefore we give for comparison also the correlation coefficient, R, and the quality factor by Cornilescu et al., $\mathrm{Q},[1]$ in all tables of the Supporting Information.

Table S2. Couplings of Cholesterol Measured in Solution ( $\left.{ }^{1} \mathbf{J}_{\mathbf{C H}}\right)$ and in the Stretched PDMS Gel ( ${ }^{1} \mathbf{T}_{\mathbf{C H}}$ ), Corresponding RDCs ( ${ }^{1} \mathbf{D}_{\mathrm{CH}}$ ) and RDCs Back Calculated with the bestFit Option of PALES (SVD-Fit) [2, 3]. All Couplings are Given in Hz

[^2]

Fig. (S2). Comparison of RDCs measured on cholesterol and back-calculated for the structures of cholesterol (left: A, C, E) and 10- $\alpha-$ cholesterol (right: B, D, F) using the -bestFit option of PALES (SVD-fit) [2, 3] (top: A, B), the cross-fitting approach with the alignment tensor determined for 5 - $\alpha$-cholestan-3-one in PDMS/CDCl ${ }_{3}$ (middle: $\mathbf{C}, \mathbf{D}$ ) and the prediction by PALES (SVD-fit) [2, 3] (bottom: E, F). The structures are shown with color-coded bonds denoting the deviation between measured and back-calculated RDCs for the different fits. The corresponding alignment tensors are visualized with their principal axis systems (black: $\mathrm{A}_{z z}$; gray: $\mathrm{A}_{\mathrm{yy}}$; white: $\mathrm{A}_{\mathrm{xx}}$ ). For all three methods the cholesterol structure (left) gives clearly the better fit. The direct SVD-fit for $10-\alpha$-cholesterol (B) results in an alignment tensor which differs most significantly from the alignment tensors for all other fits, since it tries to match RDCs measured on cholesterol to the wrong structural model (see also Figure S6). It therefore has the least ability to distinguish the diastereomers. In contrast the fit with the fixed orientation given by the alignment tensor of 5- $\alpha$-cholestan-3-one (D) shows small deviations (yellow) in regions similar to cholesterol (C-ring) and strong deviations (red) for those different to cholesterol (A- and B-ring).

Fig. (S3). Comparison of RDCs measured on cholesterol and back-calculated for the structures of cholesterol (left: A, C, E) and $10-\alpha-$ cholesterol (right: B, D, F) using the -bestFit option of PALES (SVD-fit) [2, 3] (top: A, B), the cross-fitting approach (middle: C, D) and the prediction by PALES $[2,3]$ (bottom: E, F). The plots show the back-calculated RDCs, D(calc), as a function of the measured RDCs, D(exp). Clearly the correct diastereomer cholesterol (left) is favored in all three methods.

Table S4. Couplings of $5-\alpha$-Cholestan-3-one Measured in Solution ( ${ }^{1} \mathbf{J}_{\mathbf{C H}}$ ) and in the Stretched PDMS gel ( ${ }^{1} \mathbf{T}_{\mathbf{C H}}$ ), Corresponding RDCs ( ${ }^{1} \mathbf{D}_{\mathrm{CH}}$ ) and RDCs Back Calculated with the bestFit Option of PALES (SVD-fit) [2, 3]. [^3]Table S5. RDCs Measured on 5- $\alpha$-Cholestan-3-one and RDCs Back Calculated for 5- $\alpha$-Cholestan-3-one and 5- $\beta$-Cholestan-3-one a for the bestFit Method (SVD), the Fit with Fixed Orientation Given by the Alignment Tensor of 5-a-Cholestan-3-one (Cross-fitting) and Fit with Orientation Predicted by PALES [2, 3]. Additionally Alignment Tensor Parameters and Quality Factors for the Different Fits are Given: Axial and Rhombic Components ( $\mathrm{D}_{\mathrm{a}}, \mathrm{D}_{\mathrm{r}}$ ) and Principal Axes of the Alignment Tensor ( $\mathbf{A}_{\mathrm{xx}}, \mathbf{A}_{\mathrm{yy}}, \mathbf{A}_{\mathrm{zz}}$ ) with Their Corresponding Eigenvectors (EV), Number of RDCs used for Fitting (n) and Quality Factors $\chi^{2}, \mathbf{n} / \chi^{2}$, Correlation Factor (R) and Quality Factor by Cornilescu et al. [1]. All Couplings are Given in Hz

[^4] the best result is shown).

Fig. (S4). Comparison of RDCs measured on 5- $\alpha$-cholestan-3-one and back-calculated for the structures of $5-\alpha$-cholestan-3-one (left: A, C, $\mathbf{E}$ ) and 5- $\beta$-cholestan-3-one (right: B, D, F) using the -bestFit option PALES [2, 3] (top: A, B), the cross-fitting approach with the alignment tensor determined for cholesterol in PDMS/CDCl (middle: C, D) and the prediction by PALES [2, 3] (bottom: E, F). The structures are shown with color-coded bonds denoting the deviation between measured and back-calculated RDCs for the different fits. The corresponding alignment tensors are visualized with their principal axis systems (black: $\mathrm{A}_{z z}$; gray: $\mathrm{A}_{\mathrm{yy}}$; white: $\mathrm{A}_{\mathrm{xx}}$ ). For all three methods the $5-\alpha$-cholestan-3-one structure (left) gives clearly the better fit.

Fig. (S5). Comparison of RDCs measured on 5- $\alpha$-cholestan-3-one and back-calculated for the structures of $5-\alpha$-cholestan-3-one (left: A, C, $\mathbf{E}$ ) and 5 - $\beta$-cholestan-3-one (right: B, D, F) using the -bestFit option of PALES [2, 3] (top: A, B), the cross-fitting approach (middle: C, D) and the prediction by PALES [2, 3] (bottom: E, F).The plots show the back-calculated RDCs, D(calc), as a function of the measured RDCs, $\mathrm{D}(\exp )$. Clearly the correct diastereomer $5-\alpha$-cholestan-3-one (left) is favored in all three methods.

Fig. (S6). Visualization of the alignment tensor of different steroids as obtained with the SVD method. RDCs measured on cholesterol in a stretched PDMS/CDCl $l_{3}$ gel have been fitted with the SVD method (-bestFit option in PALES) to the structural models of cholesterol (A) and its diastereomer $10-\alpha$-cholesterol $(\mathbf{C})$ and RDCs measured on 5 - $\alpha$-cholestan-3-one in a stretched $\mathrm{PDMS} / \mathrm{CDCl}_{3}$ gel have been fitted with the SVD method (-bestFit option in PALES) to the structural models of 5- $\alpha$-cholestan-3-one (B) and its diastereomer 5- $\beta$-cholestan-3-one (D). All structures are shown with color-coded bonds representing negative (red) and positive (blue) RDCs and the principle axes of the corresponding alignment tensors are drawn next to it.
Apparently the alignment tensors of cholesterol and 5- $\alpha$-cholestan-3-one in a stretched PDMS/CDCl ${ }_{3}$ gel are very similar but not fully identical. In contrast, the alignment tensors obtained by fitting experimental RDCs against the structure of a wrong diastereomer (C, D) differ significantly from those for the correct diastereomers ( $\mathbf{A}, \mathbf{B}$ ).

Out of the 18 measured RDCs of cholesterol，various subsets of $15,12,9,8,7$ and 6 RDCs were generated by random selection of RDC－ combinations．As with a decreasing number of RDCs within a subset the influence of the actual composition of the subset increases，we cre－ ated the more subsets the less RDCs are contained within the subsets．

$x=$ RDC used in this subset，$/=$ RDC not used in this subset．

To investigate the influence of the flexible side chain on the orientation predicted by PALES [2,3] we created several pdb-files of both steroids with decreasing length of the side-chain. The alkyl chain has been shortened stepwise and the resulting fragments are named after the containing carbon atoms (e.g. C1-C24 is the fragment with carbon atoms 1 to 24 and all adjacent oxygen and hydrogen atoms. Accordingly C1-C27 is the whole steroid molecule). With all steroid fragments prediction of alignment and backcalculation of the measured RDCs were performed with PALES (-stPales mode) assuming a rod-shaped alignment medium (-pf1 flag) and including all hydrogen atoms (-H flag) [2,3]. The concentration of the alignment medium (-wv flag) [2,3] which only scales the resulting RDCs linearly, was varied in steps of 0.001 to give the best result (best $n / \chi^{2}$ value).

Table S8. RDCs Measured on Cholesterol and RDCs Back Calculated for Various Cholesterol Fragments as Result of the Orientation Predicted by PALES [2, 3]. Alignment Tensor Parameters and Quality Factors for the Different Fits are Given: Axial and Rhombic Components ( $D_{a}, D_{r}$ ) and Principal Axes of the Alignment Tensor ( $A_{x x}, A_{y y}, A_{z z}$ ) with Their Corresponding Eigenvectors (EV), Number of RDCs used for Fitting (n) and Quality Factors $\chi^{2}, \mathbf{n} / \chi^{2}$, Correlation Factor (R) and Quality Factor by Cornilescu et al. [1] (Q). Additionally the Concentration (-wv) used for the Best Prediction is Given. All Couplings are Given in Hz

Table S10. RDCs Measured on Sodium Cholate and RDCs Back Calculated for Sodium Cholate with the SVD Method, the Fit with Fixed Orientation Given by the Alignment Tensor of 5- $\alpha$-Cholestan-3-one (Cross-fitting) and Fit with Orientation Predicted by PALES [2, 3]. Additionally Alignment Tensor Parameters and Quality Factors for the Different Fits are Given: Axial and Rhombic Components $\left(D_{a}, D_{r}\right)$ and Principal Axes of the Alignment Tensor ( $A_{x x}$, $A_{y y}$, $A_{z z}$ ) with their Corresponding Eigenvectors (EV), Number of RDCs used for Fitting (n) and Quality Factors $\chi^{2}$, $\mathbf{n} / \chi^{2}$, Correlation Factor $(R)$ and Quality Factor by Cornilescu et al. [1] (Q). All Couplings are Given in Hz

(a) Experimental data from Mangoni et al. [5]. As no experimental errors are given in by Mangoni et al. [5] they were set to 1 Hz for the fitting with PALES.

Fig. (S7). Structure and nomenclature of sodium cholate.

Fig. (S8). Comparison of alignment tensors for steroids in different alignment media. RDCs have been measured for cholesterol (A) and 5 - $\alpha$-cholestan-3-one ( $\mathbf{B}$ ) in stretched $\mathrm{PDMS} / \mathrm{CDCl}_{3}$ gels and for sodium cholate $(\mathbf{C})$ in a compressed $\mathrm{PAA} / \mathrm{D}_{2} \mathrm{O}$ gel. The structures are shown with color-coded bonds representing negative (red) and positive (blue) RDCs and the axes of the corresponding alignment tensors (as obtained with the -bestFit option of PALES $[2,3])$ next to it.

[^0]:    ${ }^{(a)}$ Chemical shifts are referenced to the solvent signals: $\delta{ }^{1} \mathrm{H}\left(\mathrm{CHCl}_{3}\right)=7.26 \mathrm{ppm}$ and $\delta{ }^{13} \mathrm{C}\left(\mathrm{CDCl}_{3}\right)=77.2 \mathrm{ppm}$.
    ${ }^{(b)}$ The prochiral assignment for $\mathrm{H} \alpha$ and $\mathrm{H} \beta$ protons was done with the help of measured RDCs (see tables (S2) and (S4)). Protons a and b have not been assigned to position $\alpha$ and $\beta$ wherever no or inconclusive RDCs were measured.

[^1]:    ${ }^{(a)}$ The prochiral assignment for all $\mathrm{H} \alpha$ and $\mathrm{H} \beta$ protons was determined by fitting all possible permutations with the -bestFit option of PALES [2, 3] and selecting the one with the best fitting result (in terms of highest $n / \chi^{2}$ value).
    ${ }^{\text {b) }} \mathrm{D}_{\mathrm{CH}}$-couplings of methyl-groups have been converted to the corresponding $\mathrm{D}_{\mathrm{CC}}$-couplings[4]: $\left(\mathrm{D}_{\mathrm{CC}}(\mathrm{C} 18-\mathrm{C} 13)=1.9 \pm 0.2 \mathrm{~Hz} ; \mathrm{D}_{\mathrm{CC}}(\mathrm{C} 19-\mathrm{C} 10)=1.8 \pm 0.2 \mathrm{~Hz}\right)$.
    ${ }^{(c)}$ As couplings in the D-ring did not fit in the initial fittings (see main text) they were not used in further fittings.
    ${ }^{(d)}$ Couplings measured in the flexible side chain were not used for PALES fits.

[^2]:    ${ }^{(a)} \mathrm{H} \alpha$ and $\mathrm{H} \beta$ proton assignment was permutated compared to the assignment of cholesterol. (Of all possible permutations of the prochiral methylene groups only the fit with the best result is shown.)

[^3]:    ${ }^{(a)}$ The prochiral assignment for all $\mathrm{H} \alpha$ and $\mathrm{H} \beta$ protons was determined by fitting all possible permutations with the -bestFit option of PALES [2, 3] and selecting the one with the best fitting result (in term of highest $n / \chi^{2}$ value).
    ${ }^{(\text {b) }} \mathrm{D}_{\mathrm{CH}}$-couplings of methyl-groups have been converted to the corresponding $\mathrm{D}_{\mathrm{CC}}$-couplings[4]: $\left(\mathrm{D}_{\mathrm{CC}}(\mathrm{C} 19-\mathrm{C} 10)=1.9 \pm 0.2 \mathrm{~Hz} ; \mathrm{D}_{\mathrm{CC}}(\mathrm{C} 18-\mathrm{C} 13)=1.9 \pm 0.1 \mathrm{~Hz}\right)$
    ${ }^{(c)}$ As couplings in the D-ring did not fit in the initial fittings (see main text) they were not used in further fittings.
    ${ }^{(d)}$ Couplings measured in the flexible side chain were not used for PALES fits.

[^4]:    ${ }^{(a)} \mathrm{H} \alpha$ and $\mathrm{H} \beta$ proton assignment was permutated compared to the assignment of 5- $\alpha$-cholestan-3-one. (Of all possible permutations of the prochiral methylene groups only the fit with
